

ANT INDEX

. Fireants and carpenter ants are easy to recognize for most pest control technicians. Crazy ants, Argentine ants, Pharaoh ants, Ghost ants and others can be difficult to control if they have not been identified and treated with the proper products and pest control methods.

Ant control must begin with correctly identifying the particular pest that has invaded a home, business, school or other building. After identifying your ant, you can then study pest control methods and which type of products should be used for safe elimination of ant colonies. In many cases, the ant species will dictate which products will successfully eliminate the pests. :

Pharaoh Ants should be controlled with a combination of baits. If sprays are used, the infestation will actually become worse than before.

Crazy Ants do not always respond to ant baits. In this case, a combination of contact insecticides will be needed.

Carpenter Ants can be controlled with contact insecticides or with special Carpenter ant baits. When special baits are used, the wood ants (as they are sometimes called) will do the work for you - carrying the tasty food back where it is fed to the entire carpenter ant colony. Once these pests have been brought under control, either continuing the baiting program or changing over to a spray program will prevent carpenter ants from re-investing your home.
